

Appl. No. 10/827,005  
Response Dated October 20, 2008  
Reply to Office Action dated July 16, 2008

Amendments to the Abstract

Please replace the abstract of the disclosure included in the patent application as originally filed with the following text.

A digital logger system includes a multichannel interface circuit that:

1. concurrently and continuously receives audio telecommunication signals for at least two telephone calls; and
2. continuously transmits linearly encoded digital audio data representing the received audio signals.

A Universal Serial Bus ("USB") hub of the system receives the transmitted digital data for retransmission to a USB root hub. A USB root hub of personal computer ("PC") receives transmitted digital data, and executes PC software which continuously monitors the digital data for embedded line status and signaling information including a telephone line "going off hook." When a telephone line goes "off hook," the software records both:

1. an audio header that stores information about a telephone call; and
2. an audio file that stores compressed digital data for the telephone call.
